**Introduction to Dynamic Web Content**

The World Wide Web is a constantly evolving network that has already traveled far beyond its conception in the early 1990s, when it was created to solve a specific problem. State-of-the-art experiments at CERN (the European Laboratory for Particle Physics—now best known as the operator of the Large Hadron Collider) were producing incredible amounts of data—so much that the data was proving unwieldy to distribute to the participating scientists who were spread out across the world.

At this time, the Internet was already in place, with several hundred thousand computers connected to it, so Tim Berners-Lee (a CERN fellow) devised a method of navigating between them using a hyperlinking framework, which came to be known as Hyper Text Transfer Protocol, or HTTP. He also created a markup language called HTML, or Hyper Text Markup Language. To bring these together, he wrote the first

## 16.1.1.1. The arguments array

The `arguments` array is a member of every function. With it, you can determine the number of variables passed to a function and what they are. Take the example of a function called `displayItems`. Example 16-1 shows one way of writing it.

### Example 16-1. Defining a function

```
<script>
displayItems("Dog", "Cat", "Pony", "Hamster", "Tortoise")

function displayItems(v1, v2, v3, v4, v5)
{
    document.write(v1 + "<br />")
    document.write(v2 + "<br />")
    document.write(v3 + "<br />")
    document.write(v4 + "<br />")
    document.write(v5 + "<br />")
}
</script>
```

When you call this script in your browser, it will display the following:

```
Dog
Cat
Pony
Hamster
Tortoise
```
